# Computational complexity

**Length** of the input ( $n$ ).

**Number** of lookups of the Turing machine state table.

**Function:** number of lookups versus length of input.

**Worst case** only.

$$f(n) = n \log n$$

## Average vs. worst case

Input	Algorithm A	Algorithm B
(1,2,3)	1ms	1ms
(1,3,2)	1ms	5ms
(2,1,3)	2ms	4ms
(2,3,1)	2ms	5ms
(3,1,2)	2ms	5ms
(3,2,1)	10ms	4ms
Average	3ms	4ms
Worst	10ms	5ms

Would you choose Algorithm A or Algorithm B?

## Terminology of complexity (graph)

# Linear

$$f(n) = a_0 + a_1n$$

## How many pairs of shoes does a centipede need?

- Let's say a centipede has 100 feet.
- Then every centipede needs 100 shoes.
- That's 50 pairs of shoes.
- So 2 centipedes need 100 pairs, 3 need 150 pairs, etc.
- So  $n$  centipedes need  $50n$  pairs of shoes.
- Linearity is familiar, and most people's default assumption.
- You take the input, multiply by a constant, and add another constant.

# Polynomial

$$f(n) = a_0 + a_1n + a_2n^2 + a_3n^3 + \dots$$

## What is the volume of a cube of side $n$ ?

- Suppose we have a cube with sides of length 1 metre.
- The volume of the cube is  $1 \times 1 \times 1 = 1$  metres cubed.
- Suppose the cube has sides of length 2 metres instead.
- The volume of the cube is  $2 \times 2 \times 2 = 8$  metres cubed.
- In general, for sides of length  $n$ , the volume is  $n^3$ .

# Exponential

$$f(n) = a^n$$

## How many numbers can we represent with $n$ bits?

- Consider the case of four bits – imagine four placeholders

?	?	?	?
---	---	---	---

- Each placeholder can contain either 0 or 1.
- There are  $2 \times 2 \times 2 \times 2 = 2^4 = 16$  different numbers.
- Add another bit, how many numbers is it now?
- It's  $2 \times 2 \times 2 \times 2 \times 2 = 2^5 = 32$ .
- Generally  $n$  bits can represent  $2^n$  numbers.

# Logarithmic

$$f(n) = \log_a n$$

## How many bits do we need to represent $n$ numbers?

- If we have  $n$  bits we can represent  $2^n$  numbers.
- If we want to represent  $n$  numbers, how many bits do we need (at a minimum)?
- The inverse operation to exponentiation is logarithm.
- Remember,  $a^n = b$  means  $\log_a b = n$ .

## Big-O (Sipser)

### Definition

Let  $f$  and  $g$  be functions  $f, g : \mathbb{N} \rightarrow \mathbb{R}^+$ . We say that  $f(n) = O(g(n))$ , or  $f$  is *big-O* of  $g$ , if positive integers  $c$  and  $n_0$  exist such that, for every integer  $n$  greater than or equal to  $n_0$ ,  $f(n) \leq cg(n)$ .

### Example

Let  $f$  be the function  $f(n) = 5n^3 + 2n^2 + 22n + 6$ . We'll prove that  $f$  is big-O of  $n^3$  ( $f = O(n^3)$ ). Let  $c$  be 6 and  $n_0$  be 10. Is the following true, for all  $n$  greater than or equal to 10,  $5n^3 + 2n^2 + 22n + 6 \leq 6n^3$ ? Note that as  $n$  increases ( $n = 10, n = 11, n = 12, \dots$ ),  $f(n)$  also increases. Also note that  $f(10) = 5426$  and  $6g(10) = 6000$ .

## Big-O example graph

## Smaller values of $n$
